of 1's in the binary representation. In particular $(n) \log_2(n)$. This makes a total of $(n) \log_2(n) + (n) \log_2(n)$ multiplications. We have shown: Proposition 1 Let H be a semigroup with 1. Then for all $x \in H$ and $n \in \mathbb{N}$ we can compute x^n by at most $2 \log_2 n$ multiplications. This expense is only linear in the bit length of n .
