the total number of outcomes for rolling a dice twice is $(6 \times 6) = 36$. The probability of getting an odd and even number is 18 and the probability of getting only odd number is 9. i.e., $n(A) = 18$ $n(B) = 9$.

Probability. The origin of the probability theory starts from the study of games like cards, tossing coins, dice, etc. But in modern times, probability has great importance in decision making. According to the classical theory, probability is the ratio of the favorable case to the total number of equally likely cases.

Use These Examples of Probability To Guide You Through Calculating the Probability of Simple Events. Probability is the chance or likelihood that an event will happen. It is the ratio of the number of ways an event can occur to the number of possible outcomes.

We'll use the following
